Business Analyst	John Andre Yap
Lead Developer/Tester	John Andre Yap

PART 1 - BACKLOG GROOMING

Epic Breakdown: Scratch Match - AI-Assisted Job Matcher

The "Scratch Match" epic was broken into four user stories and ranked below from highest to lowest priority.

1

High

As a Job Seeker, I want to upload my CV with a specialization label so that the system can index it and use it for AI-powered job matching.

Why this rank: Without CVs in the system there is nothing to match. This is the foundation every other feature builds on. It goes first.

2

High

As a Job Seeker, I want to see a ranked list of matching jobs for my uploaded CV so that I can focus on the most relevant opportunities in Cebu.

Why this rank: This is the core value proposition of the entire platform. It ships in the same sprint as CV upload.

3

Medium

As an Employer, I want to post a job listing so that matching candidates can discover it through the AI system.

Why this rank: Needed to populate the job pool, but the seeker side must be working first. Goes in the next sprint.

4

Low

As an Administrator, I want to view and moderate all CVs and job postings so that I can keep the platform data accurate and clean.

Why this rank: Admin tooling comes after the core seeker and employer flows are solid. Low frequency of use.

Selected Stories for the Two-Week Sprint

We selected the two highest-priority stories from the backlog:

- 1. Story 1 - CV Upload and Indexing
- 2. Story 2 - AI Job Matching

Story 1 - CV Upload and Indexing

Technical Task	Status
Design the CV upload UI: file picker, specialization dropdown, and upload progress feedback	Done
Build the PDF text extraction pipeline using PyMuPDF	Done
Chunk extracted text and embed via nomic-embed-text, store vectors in Qdrant cv_chunks	In Progress
Save Qdrant point IDs in SQLite for reliable cleanup when a CV is deleted	In Progress

Story 2 - AI Job Matching

Technical Task	Status
Design the match results UI: ranked job cards with similarity scores	To-Do
Build the matching endpoint: embed job requirements, query cv_chunks, aggregate top-3 scores	To-Do
Integrate match results into the seeker dashboard page	In Progress
Handle the empty state when no open jobs match the uploaded CV	To-Do

Visual Scrum Board - Mid-Sprint Snapshot

Calculating Average Velocity

Formula: Average Velocity = (Sprint 1 + Sprint 2 + Sprint 3) ÷ 3

Values: = (15 + 20 + 19) ÷ 3

Result: = 54 ÷ 3 = 18 story points per sprint

Avg Velocity: 18 pts/sprint

Remaining Backlog: 60 pts

Sprint Velocity Chart

Sprint Forecast

Remaining Sprints = Remaining Backlog ÷ Average Velocity

= 60 ÷ 18

= 3.33 sprints

Rounded up: the project needs approximately 4 more sprints to clear the remaining 60 story points.

1. One Benefit of Scrum Over Waterfall

One of the biggest advantages Scrum gives us over Waterfall is the ability to catch problems early, when they are still cheap to fix. In a Waterfall approach, we would have to build the entire platform - CV upload, the embedding pipeline, Qdrant integration, the matching algorithm, the employer portal, and the admin panel - before a single real user ever touched it. If the matching turned out to be inaccurate, or the CV upload flow was confusing, we would only find out at the very end.

With Scrum, we deliver a working CV upload and job matching feature in just the first sprint. A job seeker in Cebu can try it, tell us what feels off, and we fix it in the next cycle. That kind of continuous feedback loop is exactly what a platform like Scratch Match needs, where the quality of the AI recommendations is something you can only really judge by using it.

2a. Daily Standup

The Daily Standup keeps the team aligned without turning into a full meeting. Each member answers three questions: What did I finish yesterday? What am I working on today? Is anything blocking me? The whole thing runs in under 15 minutes.

During this sprint, it might sound like: one developer says they wrapped up the PDF extraction pipeline and are now wiring the chunking logic into the Qdrant collection with no blockers. Another mentions they have hit a wall on the score aggregation query because the team has not agreed on a ranking formula yet, and they need a quick sync before writing more code. That second update is exactly the kind of thing the Standup exists to surface - a blocker that would otherwise silently eat into the sprint without anyone noticing until it is too late.

2b. Sprint Retrospective

The Sprint Retrospective is a short meeting at the end of each sprint where the team asks three questions: What went well? What did not go well? What do we change next time? It is not a blame session - it is how the team actually improves from one sprint to the next.

For this sprint, we would note that the CV upload feature shipped on time because we kept text extraction and embedding as separate, independent tasks and only integrated them at the end. That approach worked well and we would carry it forward. On the other hand, the Qdrant score aggregation needed a full redesign mid-sprint because we jumped into code before the team agreed on a ranking formula. Going into the next sprint, we would make it a rule to sketch any non-trivial algorithm on paper and get a team sign-off before anyone starts implementing it.
